

Farmer Marketplace

One reliable supplier from many small farms, with a shared record of who did what. A five-page pitch.

1. The need

A restaurant, hotel or retailer wants a steady quantity of produce. A small farm has a few hundred kilos and no way to reach that buyer. The truck between them is often half empty, and the trip eats a large share of the price.

Three people lose today, so nobody can rely on anybody

Figure 1. Everyone in the chain loses a little, and together they lose the sale.

Fact	Number	Source and caveat
Transport as a share of market price	13.8% (Bangladesh, Indonesia), 27.5% (Kenya, Malawi)	ReCAP / SLoCaT rural transport factsheet, 2015, food grains. Fresh produce likely costs more.
Pooling idea	Compatible orders share one pickup and one truck	Savings are not measured yet. Real trip quotes in the pilot corridor decide the fee design.

2. Why blockchain, and only for one job

Three parties who do not know each other must agree on what happened: the farmer packed it, the transporter moved it, the buyer received it. If one company keeps that record, each party has to trust that company. A shared public record removes that single point of trust.

One shared record that none of the three can quietly edit

Figure 2. The chain keeps fingerprints and a status. Everything private stays off it.

What blockchain gives	In this app
A record nobody can quietly rewrite	Each pickup and delivery step is fingerprinted and stored in order; a retry can never add the same step twice
Settlement that anyone can check	The order ends as COMPLETED or REFUNDED, and the program refuses to flip it afterwards
A history that follows the person	Reputation built from signed steps, portable if they move to another platform
What it does NOT do	It cannot tell if the tomatoes were good. Disputes still need a person or a rule

Fast and cheap: a settle step cost 0.000005 SOL (5,000 lamports) on devnet.

3. The three layers

The farmers and buyers are the two blocks that want to trade. Transport is the middle layer that makes the trade physically possible, and gets its own pay.

Three layers: farmers and buyers are the blocks, transport is the layer between

Figure 3. Goods move left to right, payment moves right to left, the trust record sits under all of it.

Layer	Who	What they do	What they get
1	Farmers	List lots; pool with neighbours to fill a big order	A buyer they could not reach alone, paid on delivery
2	Transporters	Quote a price per trip; share a truck across orders	A fuller truck and a locked fare per trip
3	Buyers	Post demand; receive one combined supply	Steady quantity and a verified delivery record

The platform fee is planned as a capped slice of a split locked when the order is made (farmer, transporter, platform), so no one can take more later. That split is the next build stage, not live yet.

4. Partnering with local-currency exchangers and other Colosseum teams

Farmers and drivers want local money, not tokens. Buyers pay in local money too. Exchange companies that convert local currency to and from Solana-based stablecoins are the bridge. We should plug into them, and into other Colosseum teams who already built a piece.

Money path: local currency in, local currency out, with a ramp partner at each end

Colosseum teams that already solved a piece of this (examples to approach, none has agreed):

Our part is the farm-to-buyer coordination. We do not rebuild their rails.

Figure 4. We own the middle, escrow and coordination. Partners own the two ends.

Partner	What they get	What we get
Local-currency exchanger	Steady, recurring volume: every order and every payout runs through them, on both sides	Local-currency payout without building licences or banking links
Colosseum payment teams (e.g. Nomad, Ripe)	A real-world use case and transaction flow for their rails; shared story in the ecosystem	Proven local rails and users in their markets
x402 teams (e.g. MCPay), later	A paying customer for price, weather and logistics data	Paid data feeds without building them

Pitch wording: say we build on their rails and bring them volume. Do not say we want to take their users; the whole value is that we are complementary.

Status: these are proposals. No partner has been contacted or agreed. Which exchangers are licensed in the pilot country must be checked locally.

5. Where we are, and the 30-second version

Built and working	Planned
Marketplace, matching, pooled transport, trust and reputation (phases 1 to 4); API and web app live on Vercel with a Neon database. Solana program deployed to devnet; all 13 end-to-end checks pass there. Retries cannot double-record a step.	Real escrow with the locked three-way split; production on the Solana provider (today it runs a mock); chain calls moved to a background worker; Rust tests; paid RPC; multisig upgrade authority; audit.

Elevator script, about 30 seconds

"Small farmers cannot supply restaurants and shops reliably, and half-empty trucks eat a fifth of the price. We combine many farms into one supplier, match them to buyers, and pool the transport. Solana keeps a shared record of each pickup and delivery and settles the order, so no one has to trust a middleman. Farmers and drivers get paid in local currency through exchange partners, so no one needs to hold crypto. We are looking for one pilot corridor, a local-currency exchanger to partner with, and a few cooperatives and buyers to test with."

Check before you say it

Claim in the script	Make sure
a fifth of the price	Sources say 13.8% to 27.5% for grain. Say 'up to a quarter' or quote the study; replace with your own pilot quote when you have it
get paid in local currency	True only once an exchanger is signed. Until then say 'we are lining up'
Solana settles the order	Today the settlement record exists on devnet; money does not move yet. Say 'records and settles', not 'holds funds', until escrow is built

Open choices (fee level, who sets the transport price, first country, dispute rule) are in [solana-integration-ideation-v2.pdf](#) and [market-feasibility-and-pitch.pdf](#).
